

Factorization

Recall the concept of factors. From what we've learned in primary school, the factor of some number, say 18, is given by

$$\begin{aligned}18 &= 1 \times 18 \\ &= 2 \times 9 \\ &= 3 \times 6\end{aligned}$$

So, in this example, we have 1, 2, 3, 6, 9, 18 as factors of 18. Similarly, when we proceed to polynomials, the concept of factorization still works, while the computation of factorization becomes unclear and required more insights of what a polynomial is.

Let us look at the following expressions. We know that

$$x \cdot x = x^2$$

and therefore the following holds:

$$\begin{aligned}x^2 - 2x &= x(x - 2) \\ x^3 + 4x^2 &= x^2(x + 4)\end{aligned}$$

For who thinks the above expression is kind of ambiguous, let us remember the distributivity of numbers:

$$\begin{aligned}a(b + c) &= ab + ac \\ (a + b)c &= ac + ab\end{aligned}$$

and work the expressions backward. Always equip yourself with the concept that factorization is just the reverse engineering of expansion.

However, not every polynomial is simple as we have seen. For some expressions existing in Physics, we will encounter something like:

$$x^2 + 3x + 4 = 0$$

In order to find a way to solve for x , we need to learn about the methods. We will start from using identities we have learned before.

Factorization using identities

Recall the following expansion:

$$\begin{aligned}(x + y)^2 &= x^2 + 2xy + y^2 \\(x - y)^2 &= x^2 - 2xy + y^2 \\(x + y)(x - y) &= x^2 - y^2\end{aligned}$$

We should always notice that the equal sign $=$ is two-way meaningful, that is, whenever the left-hand side is equal to the right-hand side, the right-hand side is immediately equal to the left-hand side. Therefore, we may see the above in a reverse direction.

$$\begin{aligned}x^2 + 2xy + y^2 &= (x + y)^2 \\x^2 - 2xy + y^2 &= (x - y)^2 \\x^2 - y^2 &= (x + y)(x - y)\end{aligned}$$

This is called the **factorization**.

Example 1. Factorize $x^2 + 2x + 1$.

Sol.

$$\begin{aligned}x^2 + 2x + 1 &= (x)^2 + 2(x)(1) + (1)^2 \\&= (x + 1)^2\end{aligned}$$

Example 2. Factorize $x^2 + 4x + 4$.

Sol.

$$\begin{aligned}x^2 + 4x + 4 &= (x)^2 + 2(x)(2) + (2)^2 \\&= (x + 2)^2\end{aligned}$$

Example 3. Factorize $x^2 - 2x + 1$.

Sol.

$$\begin{aligned}x^2 - 2x + 1 &= (x)^2 - 2(x)(1) + (1)^2 \\&= (x - 1)^2\end{aligned}$$

Example 4. Factorize $x^2 - 4x + 4$.

Sol.

$$\begin{aligned}x^2 - 4x + 4 &= (x)^2 - 2(x)(2) + (2)^2 \\ &= (x - 2)^2\end{aligned}$$

Example 5. Factorize $x^2 - 1$.

Sol.

$$\begin{aligned}x^2 - 1 &= (x)^2 - (1)^2 \\ &= (x + 1)(x - 1)\end{aligned}$$

Example 6. Factorize $x^2 - 9$.

Sol.

$$\begin{aligned}x^2 - 9 &= (x)^2 - (3)^2 \\ &= (x + 3)(x - 3)\end{aligned}$$

We shall now be familiar with simple factorization. Let's practise with these basic identities.

Exercise

1. Factorize the following:

a) $x^2 + 6x + 9$	b) $x^2 + 8x + 16$	c) $x^2 + 10x + 25$	d) $x^2 + 16x + 64$
e) $2x^2 + 12x + 18$	f) $4x^2 + 32x + 64$	g) $6x^2 + 60x + 150$	h) $8x^2 + 128x + 512$
i) $x^3 + 6x^2 + 9x$	j) $x^5 + 8x^4 + 16x^3$	k) $x^8 + 10x^6 + 25x^4$	l) $x^9 + 16x^5 + 64x$

2. Factorize the following:

a) $x^2 - 6x + 9$	b) $x^2 - 8x + 16$	c) $x^2 - 10x + 25$	d) $x^2 - 16x + 64$
e) $2x^2 - 12x + 18$	f) $4x^2 - 32x + 64$	g) $6x^2 - 60x + 150$	h) $8x^2 - 128x + 512$
i) $x^3 - 6x^2 + 9x$	j) $x^5 - 8x^4 + 16x^3$	k) $x^8 - 10x^6 + 25x^4$	l) $x^9 - 16x^5 + 64x$

3. Factorize the following:

a) $x^2 - 9$	b) $x^2 - 16$	c) $x^2 - 25$	d) $x^2 - 64$
e) $2x^2 - 18$	f) $4x^2 - 64$	g) $6x^2 - 150$	h) $8x^2 - 512$
i) $x^3 - 9x$	j) $x^5 - 16x^3$	k) $x^8 - 25x^4$	l) $x^9 - 64x$

4. Factorize the following:

a) $x^2 + 2ax + a^2$	b) $x^2 + 8x + 16 - b^2$
c) $x^2 + 10x + 25 + y^2 - 2c + c^2$	d) $ax^2 + 16a^2x + 64a^3$
e) $2x^2 + 12xy + 18y^2$	f) $4(x + y)^2 + 32(x^2 - y^2) + 64(x - y)^2$

Factorization using more identities

For more information to using identities, we will learn more expressions to familiarize ourselves with them.

We had expressions of degree 2, so we could also proceed to that of degree 3.

$$\begin{aligned}(x + y)^3 &= x^3 + 3x^2y + 3xy^2 + y^3 \\(x - y)^3 &= x^3 - 3x^2y + 3xy^2 - y^3 \\(x + y)(x^2 - xy + y^2) &= x^3 + y^3 \\(x - y)(x^2 + xy + y^2) &= x^3 - y^3\end{aligned}$$

Just, to be clear of what is happening, we will give the expansions a clear proof.

1. For $(x + y)^3 = x^3 + 3x^2y + 3xy^2 + y^3$:

$$\begin{aligned}(x + y)^3 &= (x + y)(x + y)^2 \\&= (x + y)(x^2 + 2xy + y^2) \\&= x^3 + 3x^2y + 3xy^2 + y^3\end{aligned}$$

2. For $(x - y)^3 = x^3 - 3x^2y + 3xy^2 - y^3$:

$$\begin{aligned}(x - y)^3 &= (x - y)(x - y)^2 \\&= (x - y)(x^2 - 2xy + y^2) \\&= x^3 - 3x^2y + 3xy^2 - y^3\end{aligned}$$

3. For $(x + y)(x^2 - xy + y^2) = x^3 + y^3$:

$$\begin{aligned}(x + y)(x^2 - xy + y^2) &= x^3 + x^2y - x^2y - xy^2 + xy^2 + y^3 \\ &= x^3 + y^3\end{aligned}$$

4. For $(x - y)(x^2 + xy + y^2) = x^3 - y^3$:

$$\begin{aligned}(x - y)(x^2 + xy + y^2) &= x^3 - x^2y + x^2y - xy^2 + xy^2 - y^3 \\ &= x^3 - y^3\end{aligned}$$

Let's look at some examples to familiarize ourselves to how these work.

Example 7. Factorize $x^3 + 3x^2 + 3x + 1$.

Sol.

$$\begin{aligned}x^3 + 3x^2 + 3x + 1 &= (x)^3 + 3(x)^2(1) + 3(x)(1)^2 + (1)^3 \\ &= (x + 1)^3\end{aligned}$$

Example 8. Factorize $x^3 + 6x^2 + 12x + 8$.

Sol.

$$\begin{aligned}x^3 + 6x^2 + 12x + 8 &= (x)^3 + 3(x)^2(2) + 3(x)(2)^2 + (2)^3 \\ &= (x + 2)^3\end{aligned}$$

Example 9. Factorize $x^3 - 3x^2 + 3x - 1$.

Sol.

$$\begin{aligned}x^3 - 3x^2 + 3x - 1 &= (x)^3 - 3(x)^2(1) + 3(x)(1)^2 - (1)^3 \\ &= (x - 1)^3\end{aligned}$$

Example 10. Factorize $x^3 - 6x^2 + 12x - 8$.

Sol.

$$\begin{aligned}x^3 - 6x^2 + 12x - 8 &= (x)^3 - 3(x)^2(2) + 3(x)(2)^2 - (2)^3 \\ &= (x - 2)^3\end{aligned}$$

Example 11. Factorize $x^3 + 1$.

Sol.

$$\begin{aligned}x^3 + 1 &= (x)^3 + (1)^3 \\ &= (x + 1)(x^2 - x + 1)\end{aligned}$$

Example 12. Factorize $x^3 + 8$.

Sol.

$$\begin{aligned}x^3 + 8 &= (x)^3 + (2)^3 \\ &= (x + 2)(x^2 - 2x + 4)\end{aligned}$$

Example 13. Factorize $x^3 - 1$.

Sol.

$$\begin{aligned}x^3 - 1 &= (x)^3 - (1)^3 \\ &= (x - 1)(x^2 + x + 1)\end{aligned}$$

Example 14. Factorize $x^3 - 8$.

Sol.

$$\begin{aligned}x^3 - 8 &= (x)^3 - (2)^3 \\ &= (x - 2)(x^2 + 2x + 4)\end{aligned}$$

We shall now be familiar with degree 3 factorization. Let's practise with these basic identities.

Exercise

1. Factorize the following:

$$\begin{array}{lll}a) x^3 + 9x^2 + 27x + 81 & b) x^3 + 12x^2 + 48x + 64 & c) x^3 + 15x^2 + 75x + 125 \\ d) 2x^3 + 18x^2 + 54x + 162 & e) 3x^3 + 36x^2 + 144x + 192 & f) 5x^3 + 75x^2 + 375x + 625\end{array}$$

2. Factorize the following:

$$\begin{array}{lll}a) x^3 - 9x^2 + 27x - 81 & b) x^3 - 12x^2 + 48x - 64 & c) x^3 - 15x^2 + 75x - 125 \\ d) 2x^3 - 18x^2 + 54x - 162 & e) 3x^3 - 36x^2 + 144x - 192 & f) 5x^3 - 75x^2 + 375x - 625\end{array}$$

3. Factorize the following:

a) $x^3 + 81$

b) $x^3 + 12x^2 + 48x + 64$

c) $x^3 + 125$

d) $2x^3 + 162$

e) $3x^3 + 192$

f) $5x^3 + 625$

4. Factorize the following:

a) $x^3 - 81$

b) $x^3 - 64$

c) $x^3 - 125$

d) $2x^3 - 162$

e) $3x^3 - 192$

f) $5x^3 - 625$

Factorization using cross-method

From now on, we will dive into the main question: How to factorize any quadratic (degree 2) polynomials in the form of

$$x^2 + px + q$$

or, to be more general,

$$ax^2 + bx + c$$

using rational thinking? We shall now suppose if a quadratic polynomial $x^2 + px + q$ can be factorized into the form

$$(x + a)(x + b)$$

then it is equivalent to saying

$$(x + a)(x + b) = x^2 + px + q$$

which if we proceed one step further, the result will be

$$x + (a + b)x + ab = x^2 + px + q$$

It should be clear to see that

$$\begin{cases} a + b = p \\ ab = q \end{cases}$$

This then gives us a hint that we should perform a factorization on the constant q first, then try to figure out which pair of a, b gives the true relation on $a + b = p$.

So we may now conclude the steps of investigation and familiarize ourselves with some examples.

1. By comparing like terms, discover the p, q in the expressions.
2. Try to factorize q , state every pair of factors.
3. Check the sum of each pair of factors. If one provides a true result on $a + b = p$, then it is the true pair we need.
4. Write down $(x + a)(x + b)$ as the factorized form.

Example 15. Factorize $x^2 + 4x + 3$.

Sol. Step 1: find p and q .

$$p = 4, q = 3$$

Step 2: Factorize q (with negative pairs).

$$\begin{aligned} 3 &= 1 \cdot 3 \\ &= (-1) \cdot (-3) \end{aligned}$$

Step 3: Check $a + b = p$ (with negative pairs).

$$\begin{aligned} 1 + 3 &= 4 \\ (-1) + (-3) &= -4 \end{aligned}$$

Since $p = 4$, we have the factor pair $a = 1, b = 3$.

Step 4: Complete the factorization.

$$x^2 + 4x + 3 = (x + 1)(x + 3)$$

We could check that the factorized expression is indeed expanding back to the original polynomial.

$$\begin{aligned} (x + 1)(x + 3) &= x(x + 3) + (x + 3) \\ &= x^2 + 3x + x + 3 \\ &= x^2 + 4x + 3 \end{aligned}$$

This shows that our work is correctly given. Someone in the history consider the above steps could be refined in a compressed way of representation. We shall call it the **cross-method**.

Example 16. Factorize $x^2 + 4x + 3$ using cross-method.

Sol. As long as $3 = 1 \cdot 3 = (-1) \cdot (-3)$, we have

$$\begin{array}{rcccl}
 & x & & 1 & \\
 & \diagdown & & \diagup & \\
 & & x & & 3 \\
 \hline
 x & + & 3x & = & 4x
 \end{array}$$

That is, the factorization shows $x^2 + 4x + 3 = (x + 1)(x + 3)$.

From here, you should be familiar enough to cross-method. You may check your understanding of using cross-method by the following exercises.

Exercise

1. Factorize the following using cross-method:

a) $x^2 + 6x + 8$

b) $x^2 + 9x + 18$

c) $x^2 + 7x + 6$

d) $x^2 - 6x + 8$

e) $x^2 - 9x + 18$

f) $x^2 - 7x + 6$

g) $x^2 + 6x - 27$

h) $x^2 + 9x - 22$

i) $x^2 + 7x - 30$

j) $x^2 - 6x - 27$

k) $x^2 - 9x - 22$

l) $x^2 - 7x - 30$

2. Factorize the following using cross-method:

a) $2x^2 + 12x + 16$

b) $3x^2 + 27x + 54$

c) $5x^2 + 35x + 30$

d) $7x^2 - 42x + 56$

e) $-11x^2 + 99x - 198$

f) $-3x^2 + 21x - 18$

Solving quadratic equations by factor method

To solve quadratic equations, we acknowledge the following:

Theorem. If $ab = 0$, then either $a = 0$ or $b = 0$.

It should be clear that from above theorem, we have when $(x - \alpha)(x - \beta) = 0$, then $x - \alpha = 0$ or $x - \beta = 0$. This means the **solutions** to the equation are $x = \alpha$ or $x = \beta$.

Example 17. Solve $x^2 - 4x + 3 = 0$.

Sol. By factorization, we have $(x - 1)(x - 3) = 0$, then $x = 1$ or $x = 3$ are the solutions to the equation.

Example 18. Solve $x^2 + 4x + 3 = 0$.

Sol. By factorization, we have $(x + 1)(x + 3) = 0$, then $x = -1$ or $x = -3$ are the solutions to the equation.

We may also encounter double roots, i.e. duplicated solution to the equation. Then we can write the solution once only.

Example 19. Solve $x^2 + 4x + 4 = 0$.

Sol. By factorization, we have $(x + 2)^2 = 0$, then $x = -2$ is the solution to the equation.

Exercise

1. Solve the following equations:

a) $2x^2 + 12x + 16 = 0$	b) $3x^2 + 27x + 54 = 0$	c) $5x^2 + 35x + 30 = 0$
d) $7x^2 - 42x + 56 = 0$	e) $-11x^2 + 99x - 198 = 0$	f) $-3x^2 + 21x - 18 = 0$

2. Solve the following equations:

a) $x^2 + 6x + 9 = 0$	b) $x^2 + 8x + 16 = 0$	c) $x^2 + 10x + 25 = 0$
d) $x^2 + 16x + 64 = 0$	e) $2x^2 - 12x + 18 = 0$	f) $4x^2 - 32x + 64 = 0$
g) $6x^2 - 60x + 150 = 0$	h) $8x^2 - 128x + 512 = 0$	i) $x^3 - 9x = 0$
j) $x^5 - 16x^3 = 0$	k) $x^8 - 25x^4 = 0$	l) $x^9 - 64x = 0$

Solving quadratic equations using formula

One should observe that not every quadratic polynomial can be factorized perfectly. For example, if the equation be like:

$$x^2 + 6x - 6 = 0$$

We could see for the left-hand side, if $x = 0$, the expression computes < 0 ; if $x = 1$, the expression computes > 0 . You could imagine there must be some number $0 < x < 1$ so that the equation holds.

For exact solution, one introduced the notation \sqrt{k} for finding the solution to $x^2 = k$. It is important to remember that both positive and negative numbers can be squared to become positive, i.e. $(\sqrt{x})^2 = x$ and $(-\sqrt{x})^2 = x$ if $x > 0$.

For any quadratic equation in the form of $ax^2 + bx + c = 0$, one provides a solution in the following form:

$$\frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

where the plus or minus sign \pm indicates two solutions in one writing. This means the above formula is representing, if x satisfies the equation, then either

$$x = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \text{ or } x = \frac{-b - \sqrt{b^2 - 4ac}}{2a}$$

The origination of the formula comes from completing square method, which is quite hard to understand. We will write it down abstractly as for the proof of quadratic formula, and concrete examples will be introduced later in the section of graphs of quadratic polynomials.

Here's the proof of quadratic formula:

$$\begin{aligned} ax^2 + bx + c &= 0 \\ a\left(x^2 + \frac{b}{a}x\right) + c &= 0 \\ a\left(x^2 + 2\frac{b}{2a}x + \frac{b^2}{4a^2} - \frac{b^2}{4a^2}\right) + c &= 0 \\ a\left(x + \frac{b}{2a}\right)^2 &= \frac{b^2 - 4ac}{4a} \\ \left(x + \frac{b}{2a}\right)^2 &= \frac{b^2 - 4ac}{4a^2} \\ x + \frac{b}{2a} &= \pm \frac{\sqrt{b^2 - 4ac}}{2a} \\ x &= \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \end{aligned}$$

We will go through some usage of quadratic formula.

Example 20. Solve $x^2 + 7x - 9 = 0$ using quadratic formula.

Sol. Identifying $a = 1$, $b = 7$, $c = -9$, we have

$$\begin{aligned} x &= \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \\ &= \frac{-7 \pm \sqrt{7^2 - 4 \cdot 1 \cdot (-9)}}{2} \\ &= \frac{-7 \pm \sqrt{85}}{2} \end{aligned}$$

Example 21. Solve $2x^2 + 3x - 4 = 0$ using quadratic formula.

Sol. Identifying $a = 2$, $b = 3$, $c = -4$, we have

$$\begin{aligned}x &= \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \\&= \frac{-3 \pm \sqrt{3^2 - 4 \cdot 2 \cdot (-4)}}{4} \\&= \frac{-3 \pm \sqrt{41}}{4}\end{aligned}$$

You may now try to solve any quadratic equation using quadratic formula.

Exercise

1. Solve the following quadratic equation:

$$\begin{array}{lll}a) 3x^2 - 12x - 26 = 0 & b) 7x^2 - 27x + 54 = 0 & c) 4x^2 + 35x + 1 = 0 \\d) 2x^2 - 33x + 6 = 0 & e) -11x^2 + 89x - 18 = 0 & f) -3x^2 + 21x - 18 = 0\end{array}$$

2. Solve the following quadratic equation in terms of k :

$$\begin{array}{lll}a) 3kx^2 - x - 2 = 0 & b) 7x^2 - 27x + k = 0 & c) kx^2 + 35x + 1 = 0 \\d) 2x^2 - 3kx + 6 = 0 & e) -11x^2 + kx - k = 0 & f) -kx^2 + 21x - k^2 = 0\end{array}$$

Nature of roots: the existence of real roots

One should observe that the quadratic formula

$$\frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

consists of a square-root part, namely $b^2 - 4ac$, that affects the nature of roots very much. We gave it a name as **discriminant**, meaning the value of it discriminates the nature of roots. If this part is ≥ 0 , the quadratic formula returns a real number; if this part is < 0 , then we will be facing a square-root of negative numbers. From the history it kills a lot of mathematicians, but from now on let us define a new notion for it.

We will define a new element call i such that it satisfies the equation

$$i^2 = -1$$

and such that for any positive real number k , we can write $\sqrt{-k} = i\sqrt{k}$. We shall call i the imaginary number as it could not be thought of as a real number. For something unreal, that is imaginary.

In this sense, for if $b^2 - 4ac < 0$, we could have a suitable form of writing, in the form of $x + yi$, so that every solution to quadratic equation is well-written. We call this form of number a **complex number**, with x, y to be some real numbers.

From here let us write down the conclusion to the reality of roots using a table:

$\Delta = b^2 - 4ac$	Roots	Nature of roots
> 0	$\frac{-b \pm \sqrt{\Delta}}{2a}$	2 distinct real roots
$= 0$	$\frac{-b}{2a}$	1 double root
< 0	$\frac{-b \pm \sqrt{-\Delta}i}{2a}$	No real roots (2 complex roots)

From this we can now easily determine the nature of roots before really computing the value of the roots.

Example 22. Determine the nature of roots of the following. If it has real root(s), solve for it.

(a) $7x^2 + 5x - 10 = 0$.

(b) $81x^2 - 18x + 1 = 0$.

(c) $20x^2 + 19x + 10 = 0$.

Sol.

- (a) Checking the discriminant $\Delta = b^2 - 4ac = 5^2 - 4(7)(-10) = 305 > 0$, so it has 2 distinct real roots. By substituting the Δ back to the quadratic formula, we have

$$x = \frac{-b \pm \sqrt{\Delta}}{2a} = \frac{-5 \pm \sqrt{305}}{14}$$

- (b) Checking the discriminant $\Delta = b^2 - 4ac = (-18)^2 - 4(81)(1) = 0$, so it has 1 double real root. By substituting the Δ back to the quadratic formula, we have

$$x = \frac{-b}{2a} = \frac{18}{162} = \frac{1}{9}$$

- (c) Checking the discriminant $\Delta = b^2 - 4ac = 19^2 - 4(20)(10) = -439 < 0$, so it has no real roots.

We also notice that if we know the nature of roots for some unknown quadratic equations, we could retrieve the unknowns by drawing out propositions on the discriminant.

Example 23. *It is known that the quadratic equation $kx^2 - 4x + k = 0$ has only one real root, with real number k . Solve the equation.*

Sol. By checking the discriminant, we obtain the following:

$$\begin{aligned}(-4)^2 - 4 \cdot k \cdot k &= 0 \\ k &= \pm 2\end{aligned}$$

Therefore, the equation should be either $2x^2 - 4x + 2 = 0$ or $-2x^2 - 4x - 2 = 0$, and correspondingly having $x = 2$ and $x = -2$ as root respectively.

Exercise

1. Determine the nature of roots of the following quadratic equation:

$$\begin{aligned}a) \quad &-390x^2 - 988x + 794 = 0 \quad b) \quad 82x^2 + 290x + 759 = 0 \quad c) \quad -924x^2 - 708x + 959 = 0 \\ d) \quad &-265x^2 + 336x - 685 = 0 \quad e) \quad 845x^2 + 396x - 501 = 0 \quad f) \quad -246x^2 + 16x - 318 = 0\end{aligned}$$

2. If the following quadratic equations all have only one real root, find the value(s) of k .

$$\begin{aligned}a) \quad &kx^2 - 2x + 9 = 0 \quad b) \quad 82x^2 + kx + 79 = 0 \quad c) \quad -24x^2 - 70x + 4k = 0 \\ d) \quad &-kx^2 + 36x - k = 0 \quad e) \quad 8kx^2 + 3kx - 51 = 0 \quad f) \quad 2kx^2 + (3k - 6)x - 4k - 8 = 0\end{aligned}$$

Vieta's formula: relation between roots and coefficients

We can now further dive into some kind of abstract-nonsense. In previous section, we found that discriminant tells us the nature of the roots of the quadratic equation, and if we see the roots counted with multiplicity, the number of roots is always being equal to 2. This is not so surprising because we can always think of factorizing a quadratic equation into a product of two linear factors, so our work could be done by assuming there is always 2 roots, either they are the same or distinct.

We shall now investigate the relation between roots and coefficients, so we have a new game created by Mathematicians called algebra. Let us assume that we have a quadratic equation in the form of $x^2 + px + q = 0$, and this equation has roots α and β , which may not be real but we could still represent them using complex numbers. For if we translate the words into mathematical presentation:

$$(x - \alpha)(x - \beta) = 0 = x^2 - px + q$$

It is clear that the left-hand side is exactly equal to the right-hand side. We then expand the left-hand side to the following form:

$$x^2 - (\alpha + \beta)x + \alpha\beta = x^2 + px + q$$

This takes us to the relation between roots and coefficients by comparing like terms

$$\begin{cases} \alpha + \beta = -p \\ \alpha\beta = q \end{cases}$$

The simultaneous equations above is a system of relation called the **Vieta's formula**, which has another name called the **sum of roots** for the first equation and **product of roots** for the second equation.

In order to generalize the relationship further to any quadratic equations in the form of $ax^2 + bx + c = 0$ with real numbers a, b, c , we take the following transformation

$$ax^2 + bx + c = 0 \implies x^2 + \frac{b}{a}x + \frac{c}{a} = 0$$

so that the equation is identical to what we have investigated just a moment before by taking $p = \frac{b}{a}$ and $q = \frac{c}{a}$. Therefore, the general Vieta's formula becomes

$$\begin{cases} \alpha + \beta = -\frac{b}{a} \\ \alpha\beta = \frac{c}{a} \end{cases}$$

Example 24. Find the sum of roots and product of roots for the quadratic equation $3x^2 + 2x + 9 = 0$.

Sol. By letting α and β to be the roots of the equation, using Vieta's formula we get

$$\begin{cases} \alpha + \beta = -\frac{2}{3} \\ \alpha\beta = \frac{9}{3} = 3 \end{cases}$$

Example 25. Construct a quadratic equation with integral coefficients using $\frac{1}{2}$ and $\frac{2}{3}$ as roots.

Sol. Using Vieta's formula we get

$$\begin{cases} \alpha + \beta = \frac{1}{2} + \frac{2}{3} = \frac{5}{6} \\ \alpha\beta = \frac{1}{2} \cdot \frac{2}{3} = \frac{1}{3} \end{cases}$$

Hence, the quadratic equation we need is given by

$$x^2 - (\alpha + \beta)x + \alpha\beta = 0 \implies x^2 - \frac{5}{6}x + \frac{1}{3} = 0 \implies 6x^2 - 5x + 2 = 0$$

Exercise

1. Find the sum of roots and product of roots for the following quadratic equations:

$$a) -390x^2 - 988x + 794 = 0 \quad b) 82x^2 + 290x + 759 = 0 \quad c) -924x^2 - 708x + 959 = 0$$

$$d) -265x^2 + 336x - 685 = 0 \quad e) 845x^2 + 396x - 501 = 0 \quad f) -246x^2 + 16x - 318 = 0$$

$$g) kx^2 - 2x + 9 = 0 \quad h) 82x^2 + kx + 79 = 0 \quad i) -24x^2 - 70x + 4k = 0$$

$$j) -kx^2 + 36x - k = 0 \quad k) 8kx^2 + 3kx - 51 = 0 \quad l) 2kx^2 + (3k - 6)x - 4k - 8 = 0$$

2. Construct, for each pair of roots stated below, a quadratic equation with integral coefficients respectively.

(a) $\frac{2}{5}$ and $-\frac{6}{7}$.

(b) $\frac{3}{2}$ and $\frac{7}{4}$.

(c) 4 and -4.

(d) 5 and $-\frac{2}{7}$.
